

Do Private Regulations Ratchet Up?: How to distinguish types of regulatory stringency and patterns of change*

May 16, 2019

Due to inconsistent measures of regulatory stringency, scholars offer conflicting accounts about whether competing private governance initiatives “race to the bottom,” “ratchet up,” “converge,” or “diverge.” To remedy this, we offer a framework to distinguish three often-conflated measures: regulatory scope, prescriptiveness, and performance levels. We use our framework to compare competing U.S. forestry certification programs, one founded by environmental activists and their allies, the other by the American Forest & Paper Association. We find “upward” but also divergent policy prescriptiveness, with the activist-founded program adding requirements that impose costs on firms and the industry-backed program mostly adding requirements with net benefits to the sector. These results are consistent with the hypothesis that industry-backed programs emphasize less costly types of stringency than activist-backed programs. Furthermore, we find several more nuanced patterns of change that previous scholarship failed to anticipate, illustrating how disentangling types of stringency can improve theory building and testing.

Keywords: policy change, private authority, certification, corporate social responsibility, private governance

*We are grateful to reviewers of earlier versions of this paper presented to the American Politics Workshop at the University of Wisconsin-Madison, the Association of Public Policy Analysis and Management (APPAM) Annual Research Conference, and the Association of Environmental Studies and Sciences Annual Meeting. We are also grateful to extensive feedback on a 2014 draft of the analytic framework and the underlying data tables from officials from the Forest Stewardship Council (FSC), the Sustainable Forestry Initiative (SFI), and the Program for the Endorsement of Forest Certification (PEFC). We are grateful for funding from the Fox Foundation, Procter & Gamble, Staples, Office Depot, and Arup. We also thank Erica Pohnan and Akiva Fishman for research and editing assistance. The authors are fully responsible for data collection, analysis, and any errors. Comments welcome: JudgeLord@Wisc.edu. The most recent version of this paper is available at <https://judgelord.github.io/FSC-SFI/oe/certification.pdf>.

1 INTRODUCTION

Private governance initiatives, such as product certification programs, have targeted farm and factory working conditions, greenhouse gas emissions, and fishery, mine, and forest management (Auld, 2014; Bartley, 2003; Bozzi et al., 2012; Hudson and Hudson, 2003; van der Ven, 2015; Vince and Haward, 2017). Many of these programs were founded by activists who were dissatisfied with public regulations. Using tactics such as boycotts as “sticks” and brand-boosting praise as “carrots,” activists attempt to pressure companies to comply with certification programs that go beyond the requirements of public laws (Cashore, 2002). When buyers add certification criteria to their purchasing policies and contracts, those certification programs gain power to regulate how commodities are produced. Industry groups often resist these efforts at private (i.e. non-state) regulation, in some cases launching competing certification programs to offer more “business-friendly” alternatives.

Debates among supporters of activist-backed programs and industry-backed alternatives often center on the relative stringency of each program’s regulatory requirements. Compared to governments, which enjoy sovereign authority, it is especially vital for private organizations to achieve and maintain legitimacy in the eyes of both those they aim to empower and those they seek to regulate (Bartley, 2007; Bodansky, 1999; Cashore, 2002). One way they achieve and maintain legitimacy is through claims about the stringency of their requirements.

Concepts of regulatory stringency are also at the center of conflicting theoretical and empirical claims from scholars across political science, economics, and sociology about the potential effects of these programs and how and why they evolve. A key motivation behind this research is understanding whether the social and market forces driving private regulations lead to similar patterns observed in public regulations, such as a “race to the bottom” as governments attempt to attract capital, a “race to the middle” as shared expectations emerge, or a “race to the top” as companies operating in areas with more stringent regulations lobby to equalize requirements across jurisdictions (Berger and Dore, 1996; Rodrik et al., 2004; Vogel,

1995). While private governance scholars have made great strides, imprecise, incomplete, and inconsistent measures of regulatory stringency have hindered efforts to compare these regulations and assess theories about why they change. We argue that more attention to measurement can explain seemingly contradictory findings and allow for more tractable statements of theory. To be sure, concepts of regulatory stringency interest students of both public policy and private governance, but whereas a rich public policy scholarship has emerged to measure and explain public policy change (Green-Pedersen, 2007; Hall, 1993; Howlett and Cashore, 2014), private governance scholarship gives much less attention to the concept of policy change.

To address this gap, we build on taxonomies from the public policy literature to offer a two-part framework to describe and compare regulations over time. Part one of this framework distinguishes three types of regulatory stringency: 1) How comprehensive is the scope of issues addressed? 2) How prescriptive are the requirements? 3) What are the specific levels of performance required? Part two offers a method to classify changes across programs, yielding nine possible patterns to describe both relative and absolute directions of policy change. This approach provides a common language to describe how various regulations in the same policy space may change over time. Such research is especially important where multiple programs, backed by different coalitions, compete to exercise regulatory authority. Distinguishing among types of regulatory stringency and patterns of change leads to hypotheses that are more conceptually precise and thus more tractable for empirical testing than those advanced by extant literature.

We proceed in the following steps. Section two maps the different concepts and measures of regulatory stringency in existing private governance scholarship. Section three presents our framework to distinguish three types of stringency and compare them across programs and over time. Section four applies the framework to compare competing certification programs in the U.S. forestry sector, arguably one of the most institutionalized cases of private regulation. Section five discusses the implications of our results for theory and outlines steps for future

research.

2 REGULATORY STRINGENCY

Measuring regulatory stringency is often necessary to assess how activist campaigns, market forces, and competition among programs shape policy content (i.e., regulatory requirements as the dependent variable), and likewise, to assess how policy content shapes activist support, market adoption, impact, and how other programs respond (i.e., regulatory requirements as the explanatory variable).

Stringency as an explanatory variable: Scholars who study how private regulations gain legitimacy, trust, or support from various audiences posit that regulatory stringency is a key explanatory variable for these outcomes. For example, McDermott (2012) argues that stringency may reduce trust by mandating formulaic, top-down approaches. Perceived stringency may increase market demand for certified products (Atkinson and Rosenthal, 2014), but finds may also reduces adoption by firms (Prado, 2013). Changes in stringency that disadvantage some firms or groups may catalyze these actors to create alternative private regulatory programs (Meidinger, 2003). Alternatively, those disadvantaged by changes to private regulation may then opt to pursue their aims through public policy (Weimer, 2006). Such outcomes would be consistent with broader findings from literatures on “corporate social responsibility” (CSR) initiatives, such as environmental management systems (EMS), industry codes of conduct, and third-party certification programs, which find that more costly requirements are less likely to be adopted (Delmas and Montiel, 2008; Kollman and Prakash, 2001; Lyon and Maxwell, 2008).

The effects of stringency on trust, legitimacy, compliance cost, and adoption matter because understanding the likely future impact of private regulations “on the ground” requires understanding their evolutionary trajectories (van der Ven et al., 2018). Even activist-backed programs that establish stringent requirements on one issue at one point in time may not do so on other issues and at other times (LeBaron and Burgoon, 2018). Nuanced gaps in

otherwise stringent private regulations—“regulatory loopholes”—may also explain their lack of success in addressing problems like deforestation (van der Ven et al., 2018). Together, these studies suggest that changes in regulatory stringency *may* have a wide range of effects. Sadly, assessing them has been hampered by inadequate attention to defining and measuring stringency as an explanatory variable.

Stringency as a dependent variable: Regulatory stringency is also a key variable in studies of the reverse causal relationships: how ideological, economic, political, and social forces shape and constrain policy content (Bartley, 2003; Cashore et al., 2004; Fischer and Lyon, 2014). Scholars theorize that various forces either promote or hinder stringent regulation. For example, ideas about the political responsibilities of businesses shape both activist demands for private governance and firms’ responses to private governance efforts (Bartley, 2003; Djelic and Etchanchu, 2017). These different ideas are then embodied in more or less stringent policies depending on which coalitions gain rulemaking authority (Botzem and Dobusch, 2012; Hsueh and Prakash, 2012). Bartley (2003) finds private regulations emerging when social movements target companies with tactics that aim to redirect, rather than challenge, neo-liberal ideas. Others find private regulations arising from collective action by industry to preempt or replace more stringent government regulations (Bartley, 2007; Cashore, 2002; Grabosky, 2013; Green, 2013; Loconto and Fouilleux, 2014; Lyon and Maxwell, 2008; Maxwell et al., 2000; Prakash, 2000). Abbott and Snidal (2009) suggest that the content of public and private regulations are a joint result of bargaining between activists and firms. The common thread is that each of these studies aims to explain relative differences or changes in policy.

Others seek to explain variation in regulatory stringency as a result of endogenous interactions among private authorities (DeLeon and Rivera, 2009; Eberlein et al., 2014; Green, 2017; Gulbrandsen, 2014; Howard-Grenville et al., 2008; Li and van ’t Veld, 2015; Mills, 2016). For example, Smith and Fischlein (2010) suggest that competing private regulations change frequently and often imitate each other. Similarly, Eberlein et al. (2014) identify “frequent rule revision” or “differentiation among rule systems” as potential effects of such interaction.

A related body of scholarship seeks to explain regulatory stringency as a result of strategic interactions among the coalitions backing different programs. Some focus on how competition may lead to more “weak or lax standards” as firms “shop” for lower-cost programs, potentially causing a “race to the bottom” (Abbott and Snidal, 2010; Fransen, 2011; Gulbrandsen, 2004). In contrast, others find competition causing “weak” regulations to be “revised upwards” as activists invite public comparisons with the requirements of “higher” regulations (Overdevest, 2005, 2010). And still others find both patterns occurring, depending on market and industry structures (Cashore et al., 2004; Hassel, 2008; van der Ven, 2015). Cashore et al. (2004) highlight how market and institutional logics initially work to pressure coalitions to “lower” stringency but then, later, work to maintain differences.

Concepts of regulatory stringency are also at the core of formal models of private governance. Models by Abderrazak and Youssef (2009) and Fischer and Lyon (2014) suggest that standards may increase or decrease stringency under different conditions, such as increases or decreases in compliance costs or market demand. Game-theoretic models (Fischer and Lyon, 2014; Li and van ’t Veld, 2015; Poret, 2016) and empirical research (Cashore et al., 2004) both suggest that asymmetric incentives lead competing programs to adopt different levels of stringency in equilibrium. Where an activist-backed regulation competes with an industry-backed regulation, these theories predict that the activist-backed program will ultimately be more stringent.

Assessing theories that aim to explain changes in regulatory stringency has been hampered by inadequate attention to the dependent variable they seek to explain. The contradictions are most striking in the patterns of change these studies claim to find. Some posit—and find evidence for—a pattern where competing regulations “ratchet up” and less stringent regulations converge toward more stringent ones (Overdevest, 2005, 2010; Overdevest and Zeitlin, 2014). Other scholars posit—and find evidence for—the exact opposite pattern, in which competitive pressures lead a “race to the bottom” with more stringent programs decreasing stringency and converging toward less stringent ones in (Abbott and Snidal, 2010;

Fransen, 2011; Gulbrandsen, 2004). Still others posit—and find evidence for—yet another pattern where programs maintain different levels of stringency, i.e., they remain distinct, neither converging to the “top” nor the “bottom” (Fischer and Lyon, 2014; Li and van ’t Veld, 2015; Poret, 2016; Cashore et al., 2004). While these three sets of findings seem incompatible, we argue that they are the result of different measurement strategies. Reconciling them thus requires a set of shared concepts and measures of regulatory stringency.

2.1 CONCEPTS & MEASUREMENT OF VARIATION IN PRIVATE REGULATIONS

The diversity of private governance scholars’ conceptual and empirical approaches to measuring regulatory stringency makes this literature vibrant but confusing: Some scholars evoke vertical notions of variation, describing standards as high or low or more or less stringent (Fischer and Lyon, 2014; Li and van ’t Veld, 2015). Others evoke horizontal notions of variation, describing the width or breadth of issues covered (Auld, 2014; Heyes and Martin, 2017). Cashore and Howlett (2007) call attention to variation in prescriptiveness versus flexibility, i.e., the extent to which regulations use mandatory and substantive performance thresholds. Others measure height in a relative sense, defining the “benchmark” as the higher standard (Overdevest, 2005, 2010). Still others combine concepts of breadth and prescriptiveness into one broader notion of stringency (Fransen, 2011). These distinct dimensions of stringency are often conflated. For example, formal models often assign each program a single overall “quality” or “stringency” parameter that could be measured multiple ways yielding different empirical results. And these are only a few of the many measures of stringency used in this literature, ranging from so broad that they conflate many of these concepts to so narrow that they measure only a few select components of just one (see Table 1).

Overall, concepts of stringency in existing work tend to be either insufficiently precise to be consistently applied across programs, insufficiently comprehensive to yield consistent results, or completely absent. Similar problems plague public policy scholarship (Brunel and Levinson, 2016).

Table 1: Concepts and Measures of Regulatory Stringency

Selected Scholarship	Concept (arranged narrow to broad)	Measurement orientation
García-Montiel et al. (2017)	“more rigorous,” “higher level,” “higher quality,” and thus “Greater complexity/Effectiveness/Cost” vs. “More Simplicity/Lower Cost”	Number of indicators. Descriptions of consistency, coherence, and completeness.
Moore et al. (2012)	Management practices changed	Survey of self-reported number and type of practices implemented
McDermott et al. (2010)	“comprehensiveness and prescriptiveness”	Number of key issues with most prescriptive language
Overdevest and Zeitlin (2014)	“far apart” or “closer” on select “Characteristics”	Binary table of select issues and descriptive examples
Overdevest (2010)	“comparative quality” “weaker” are “revised upwards” to be “equivalent” to “higher and more prescriptive standards”	Descriptive theory, examples, and review of previous comparisons
Fransen (2011)	“stringency” as “comprehensive in scope, specific in content, and prescriptive in terms of requirements”	Description based on “leading policy analysts per issue area”
Hansen et al. (2006)	Select “general features” and “six aspects” of management	Descriptive table of select issues
Auld (2014)	“Policy scope and regulatory domain,” “policy changes,” “character of the rules developed”	Description of the set of problems addressed and how
Cashore et al. (2004)	“stringency”	Descriptive theory, examples
Smith and Fischlein (2010)	“stringency” of “weightings across multiple, and often conflicting, attributes,” also “excellence in content”	Descriptive theory, examples
Porter (2014)	“hard law” or “soft law”	Descriptive examples
Gulbrandsen (2004)	“variations in the strength”: “more stringent and less discretionary,” “more rigorous and wide-ranging” vs. “weak or lax” with “wider flexibility” Some “regulations have become more flexible” while others are “changing upward”	Descriptive examples
Eberlein et al. (2014)	“differentiation” along “dimensions of regulatory governance,” e.g. “more or less stringent” or “regulatory capacity”	Descriptive typology, examples
Hassel (2008)	“high and low quality regulation,” “higher standards” vs. “lower standards”	Descriptive theory, examples
Bartley (2003)	“more credible claims” vs. “lax standards”	Descriptive theory, examples
Abbott and Snidal (2009)	“regulatory outcomes” “stringent” “higher standards” vs. “less stringent” “business-friendly” “weaker standards”	Descriptive theory
Bernstein and Cashore (2007)	Pressure to “raise” or “lower” requirements “explains convergence/ divergence”	Descriptive theory
Kollman and Prakash (2001), Potoski and Prakash (2005)	“lax” or “processes-based” vs. “more stringent” “outcome-based” or “product-based” “types of regulations”	ISO14001 classified as process-based, stringency assessed only for public regulations
Prakash and Potoski (2007)	“stringent” vs. “lenient”	Costs, social externalities, and branding benefits
Formal models of “stringency” or “quality”	“sustainability quality level” (Poret, 2016), “stricter rules” (Schmitz et al., 2017), “stringency” (Fischer and Lyon, 2014)	Costs vs. benefits to programs & firms
Formal models of issue scope	“issue-width” in an “issue space” (Hayes & Martin 2015)	Costs vs. benefits to programs and funders

In the absence of consistent measures of regulatory stringency, scholars have turned to proxy measures. For example, Darnall et al. (2010) suggest that a program’s sponsor is a signal of its stringency. In the broadest study to date, van der Ven (2015) uses another common proxy for stringency—compliance with perceived “best practices,” which are often also considered “benchmarks” for measuring stringency but are based on a variety of different notions of “rigor” and “credibility.” However, these approaches do not allow scholars to examine relationships between stringency and program sponsorship or between stringency and perceived stringency.

More importantly, different approaches to measuring regulatory stringency prevent us from adjudicating between claims that competing programs will “race to the bottom,” “ratchet up,” “converge,” or “diverge.” Indeed, different measurement strategies explain the seemingly contradictory evidence in favor of each theory. While van der Ven (2015) does find support for the prediction that activist-backed private regulations are more likely to align with “best practices” but does not find support for the prediction that industry-backed regulations are less likely to do so. The latter finding seems to contradict findings by Cashore et al. (2004) that industry-backed programs set less stringent requirements. However, this is due to differences in measurement; Cashore et al. focus on the substantive prescriptiveness of regulations governing operations, while van der Ven focuses on stakeholder engagement and others forms of procedural “best practices.”

Two common challenges have hindered efforts to identify patterns of change. First, results vary depending on the policy components studied. Even the handful of scholars who have developed direct and precise measures of stringency (the top of Table 1) tend to only focus on a few salient policy components, rather than attempting to assess the entire range of requirements that regulations address. This approach can lead to conflicting results if scholars select different policy components as indicators of stringency. For example, to compare forestry certification programs, Cashore et al. (2004) assess prescriptiveness on seven issues related to ecological protection (plantations, chemicals, clearcuts, exotics, reserves, streamside

riparian zones, and genetically modified organisms) and find large enduring differences between activist-backed and industry-backed programs. In contrast, Overdevest and Zeitlin (2014) find that these same program “all moved closer” by assessing whether or not each program addressed six other features—two substantive requirements on firm behavior (public reporting and stakeholder consultation), two on compliance mechanisms (auditing and supply chain tracking), and another two on decision-making and marketing strategy—finding policy convergence on all six. Here, different measurement strategies led to different conclusions that appear to support conflicting theories of policy change. It is entirely plausible that if Overdevest and Zeitlin had chosen Cashore et al.’s set of issues or vice versa, each might have found the opposite pattern.

Second, binary indicators such as whether or not a program addresses a given topic—i.e. “is this issue in the program’s scope?”—fail to capture variation in degree—e.g., “how high is the threshold set” (what is the required frequency of public reporting or prohibited amount of pollution?) and “how prescriptive are they?” (How much is voluntary versus mandatory?). The scope of requirements, degree of prescriptiveness, and levels of thresholds are important but orthogonal dimensions of variation that may exhibit different patterns of change for different reasons. Overdevest and Zeitlin (2014) assert that the industry-backed program moved in the direction of the activist-backed program within the *scope* of issues related to public reporting and consultation, while Cashore et al. (2004) found that these competing programs did not converge in *prescriptiveness* on issues related to ecological protection. The apparent conflict between Overdevest and Zeitlin’s study and Cashore et al.’s study is thus largely resolved by distinguishing findings about the scope of issues covered versus the prescriptiveness of regulatory requirements.

If selection and measurement decisions explain variation in findings, the remedy is methods that allow more systematic comparisons. We address this need by offering a framework to (1) measure three types of stringency and (2) characterize change over time.

Table 2: Types of Regulatory Stringency

	Program Level	Issue Level
Policy Ends	How comprehensive is the scope of issues addressed?	What are the specific requirements (i.e. policy settings) on each issues? (e.g. the specific size of stream buffer zones)
Policy Means	In aggregate, across all issues, how prescriptive is each regulation? To what extent (e.g. on what portion of issues) are there mandatory and substantive thresholds?	1. How prescriptive is each requirement? 2. How are requirements enforced? (*Beyond the scope of this paper)

3 A FRAMEWORK TO CLASSIFY CHANGE IN PRIVATE REGULATIONS

The first step for scholars who wish to make claims about stringency involves three tasks: describing policy content according to policy settings, scope, and prescriptiveness (Table 2). Comparing across programs requires a second step: measuring relative stringency and change on each dimension (see Table 4). First, we elaborate on step one.

3.1 STEP 1: MEASURING SCOPE, PRESCRIPTIVENESS, AND POLICY SETTINGS

We focus on three dimensions of variation: (1) the comprehensiveness of a regulation’s scope (i.e. which policy problems it addresses), (2) the extent to which requirements are prescriptive versus flexible (i.e., whether they have mandatory and substantive thresholds), and (3) the levels of those thresholds or similarly specific policy settings. Our framework thus combines qualitative issue-by-issue comparison of policy settings with two measurement concepts—policy scope and policy prescriptiveness—that can be applied across issue areas and thus aggregated to measure overall stringency. That is, by comparing the number of issues covered by a regulation and the number of prescriptive requirements on those issues, scholars can assess aggregate trends.

Scope: Given the differences within and across programs, assessing the relative scope of

issues they address requires inductively deriving a full range of policy issues addressed by one or more regulatory texts in a given policy domain. All comparisons of scope are conditional on such a set that establishes the “denominator” in the portion issues addressed by each program at each point in time. Scholars often give too little attention to this set of relevant comparisons given its importance in determining results. Once a researcher establishes a comprehensive set of issues, they can turn to assess the extent to which each regulation covers this set of issues.¹ With the measurement concept of issue scope, one can assess a regulation’s absolute requirements (i.e., how many key issues it addresses); its relative requirements (i.e., how many more or fewer issues does it address than its competitor), and in change over time (i.e. how many changes occurred between time 1 and time 2).

Prescriptiveness: Second, we measure the extent to which each requirement is prescriptive, i.e., has substantive and mandatory features such as performance thresholds (see Table 3 adapted from Cashore and Howlett (2007)). In forestry, thresholds include the maximum size of permitted clearcuts or minimum size of buffer zones around streams. Because “prescriptive versus flexible” refers to how each issue is addressed (whether a regulation has mandatory thresholds), not the ends of the policy (the levels of those thresholds), we can compare prescriptiveness across substantive requirements.

Prescriptiveness is a continuum. Discretionary guidelines, practices, processes, or plans are least prescriptive because they allow maximum flexibility. Procedural requirements that prescribe processes that must be followed but do not prescribe outcomes are somewhat prescriptive. Mandatory and substantive requirements, such as quantitative performance thresholds, are most prescriptive because they prescribe precise actions and outcomes. Compared to mandatory performance thresholds, even mandatory requirements to follow local “best management practices” are less prescriptive because these practices may not include substantive requirements.

On each issue, our framework identifies both absolute and relative measures of prescriptiveness. This leads to three possibilities: “no prescriptive requirements” or “some prescriptive

Table 3: Prescriptiveness of Policy Types

	Discretionary	Non-discretionary
Procedural (plan- or systems-based)	Flexible	Somewhat prescriptive
Substantive (e.g. a policy threshold)	Flexible	Most prescriptive

requirements”—and then, if the latter, whether they are “most prescriptive” (requiring as much as or more than any other regulation). Coding prescriptiveness across issues creates an additional measure of policy scope: how many key issues have “some prescriptive standards.” Coding prescriptiveness across programs creates a measure of the relative level of prescriptive requirements. Additionally, our framework classifies changes as becoming more prescriptive or less prescriptive on each issue, thus capturing the direction of change in prescriptiveness.

Policy settings: Finally, the third type of stringency—specific performance levels (what policy scholars call “policy settings”)—allow us to interpret differences in scope or prescriptiveness substantively. For example, forestry certification programs have different requirements for how close loggers can harvest near streams. In this example, all standards prescribing minimum stream buffer widths are equally prescriptive since all are mandatory requirements, albeit with different thresholds. Yet buffer widths and other specific policy settings are a meaningful type of variation. Unfortunately, most specific policy settings, even prescriptive ones, cannot be quantified and are thus difficult to aggregate. Even numeric stream buffers are difficult to compare because they often vary in different contexts, for example in mountainous or flat areas, and involve different levels of harvest restrictions based on different criteria, such as whether fish live in the stream (see Figure 5 in section 4). Measurement strategies that allow program-level aggregation cannot replace issue-specific qualitative comparison. It is crucial to both quantify absolute and relative differences and describe the most meaningful differences that capture the overall trends. We thus suggest that scholars combine aggregate measures with descriptive comparisons of important requirements, assessing each issue in an absolute sense, in a relative sense (if possible), and in how the required level of performance changed.

At its most stylized, step one, comparing two hypothetical programs (A and B) in a policy space with two issues (Hazardous Chemicals and Worker Training) might look like this: A researcher examines regulations in this policy area and inductively identifies a total of two issues. Both programs have some prescriptive requirements on both issues, so they are equal in scope. Program A bans using chemicals above certain quantitative toxicity thresholds, whereas Program B bans “hazardous” levels which auditors could interpret several ways, so Program A is more prescriptive on the issue of Chemicals. For policy settings, the two programs ban slightly different lists of chemicals, Program A focusing on ecologically harmful chemicals and program B targeting those most harmful to humans, so the researcher can only compare their specific requirements on chemicals qualitatively. On the second issue, both programs require mandatory worker training programs, and neither specifies how many hours, so they are equally prescriptive on Training. Each program suggests a slightly different list of topics for training to cover. Program A focuses more on skills needed to avoid ecological harm, and Program B focuses more on worker safety, so again, the researcher can only compare their policy settings qualitatively. Yet a pattern emerges: Program A, the overall more prescriptive program, is also more focused on ecological protection, possibly due to being more influenced by environmental activists. In contrast, program B is more focused on worker safety, possibly to reduce the risk that worker injuries at one firm will impose reputational or regulatory costs for the whole industry.

As this example illustrates, the combination of precise and comprehensive measurement can avoid problems with using any one approach alone. Measuring scope alone risks overlooking variation in prescriptiveness and levels of performance required. Measuring prescriptiveness alone risks capturing a kind of stringency that is void of content. And comparing a few specific performance levels alone risks missing the broader picture, or worse, making overly broad generalizations where a different set of issues would yield different overall conclusions.

3.2 STEP 2: CLASSIFYING PATTERNS OF CHANGE

Building on Baumgartner (2002) and Howlett and Cashore (2007), we also emphasize the importance of the direction of policy change. Assessing patterns of change like punctuation or equilibrium requires measuring change on each dimension of stringency because there may be equilibrium on one dimension but punctuation on another. In absolute terms, stringency may be increasing, decreasing, or neither, and, in relative terms, regulations may be converging, in equilibrium, or diverging on each dimension over any given period (Table 4). Thus, in aggregate, nine relationships fully capture the possible dynamics for each dimension of change. All of the theories about regulatory stringency from Table 1 should be able to be expressed in terms of the dimension(s) to which the theory applies, the absolute directions of change they predict, and relative relationships they anticipate.

Table 4: Possible Patterns of Change in Relative Stringency

		Relationship Among Standards		
		Converging	Parallel	Diverging
Directions of Change (in comprehensiveness of scope, prescriptiveness, or levels of requirements)	Increasing			
	Opposite or Equilibrium			
	Decreasing			

*The two arrows in each cell represent two programs.
A study of three programs would have three arrows.

Conclusion: This framework for measuring regulatory stringency helps researchers accomplish several important tasks. For example, Brunel and Levinson (2016) argue that a measure of regulatory stringency must: (1) measure change over time, (2) assess both relative and absolute magnitudes, (3) aggregate across multiple issue areas, and (4) be theoretically relatable to compliance costs. To these criteria, we add that any measurement approach should also (5) capture qualitative differences in policy settings. Step one satisfies these five criteria and step two goes on to classify relative change over time.

3.3 THEORIZING IN TERMS OF SCOPE, PRESCRIPTIVENESS, AND POLICY SETTINGS

Our core methodological critique is that different dimensions of stringency may exhibit different patterns of change. Precise and testable hypotheses about the causes and effects of change must distinguish among types of policy change. If different dimensions of regulatory stringency vary independently, a vast array of theories that use stringency as an explanatory or dependent variable must be revised to specify the dimension(s) to which they apply. Revisiting theories in terms of scope, prescriptiveness, and policy settings may yield different predictions on each dimension. It is beyond the scope of this paper to revisit all hypotheses in this vast literature in light of our methodological critique, but, for illustrative purposes, we offer examples of such a restatement for hypotheses rooted in compliance cost and differentiation.

Compliance costs and competition: By breaking down stringency into three distinct dimensions, we expand on two related propositions: (1) Compliance costs cause competing programs to set different levels of stringency. Specifically, Cashore et al. (2004) and Fischer and Lyon (2014) theorize that industry-backed programs set less stringent regulatory requirements than activist-backed programs because industry-backed programs are less willing to impose costs on firms. (2) Programs change in response to changes by their competitor. Specifically, when private authorities compete for market share, if one changes its requirements, the other will change in a similar direction (Fischer and Lyon, 2014; Smith and Fischlein, 2010). Yet, these studies do not specify which dimensions of stringency ought to be affected by compliance costs. Do incentives rooted in compliance cost affect each dimension in the same way? Are competing programs more responsive to changes in the scope, prescriptiveness, or policy settings of competing standards? Disentangling policy settings, scope, and prescriptiveness suggests more precise hypotheses to assess such theories rooted in compliance cost and competition.

Revised compliance cost hypotheses: If broadening scope is low-cost for firms but increasing prescriptiveness and performance levels are high-cost,

H1.1: An industry-backed regulation will be more similar to an activist-backed regulation in scope than in prescriptiveness or performance levels.

H1.2: An industry-backed regulation will be more likely to respond to changes in an activist backed regulation by converging in scope than in prescriptiveness or performance levels.

Differentiation: Another core theoretical claim is that different coalitions will establish qualitatively different policies (Botzem and Dobusch, 2012; Hsueh and Prakash, 2012). By distinguishing types of stringency, we identify qualitative differences in how stringency varies across programs.

Specifically, we expect that the relative stringency of an industry-backed program on a given issue will depend on whether the requirements results in net benefits to the industry. In contrast, we expect activist-backed programs to target issues where requirements impose costs on firms to achieve social or ecological goals. On these issues, industry-backed programs have different incentives; they will be balancing their need to maintain legitimacy in the eyes of buyers with their need to minimize compliance costs for the industry. The result is likely to be a lower level of stringency than that of an activist-backed program, even as they both change over time. We would also expect this difference between programs to be larger on issues where compliance costs are relatively higher or where industry-backed programs can more easily foster an impression of stringency without imposing costly requirements.

The opposite result is likely on issues where requirements provide net benefits to the industry. Here, activist-backed programs have little incentive to develop stringent requirements because activist pressure is redundant. These “business-friendly” issues are frequently addressed by industry associations. They include coordinating resources and solving collective action problems related to industry reputation (e.g., through public image campaigns) and capacity (e.g., by developing collective goods like technical knowledge or a skilled workforce). By “collective action,” we merely mean actions across individuals or firms that have net benefits but that requires a coordinating institution. Like industry associations, certification

programs can serve as coordinating institutions. Business-friendly certification programs may also attempt to boost perceptions of stringency by adding requirements to do things that firms would do anyway. If observers fail to distinguish among different types of stringency on different issues, such a strategy may be a low cost and effective way to shape perceptions of overall stringency.

Revised differentiation hypotheses: Where activist-backed and industry-backed private regulations compete,

H2.1: Activist-backed regulations will have more comprehensive coverage, more prescriptive requirements, and higher performance thresholds on costly issues.

H2.2: Industry-backed regulations have more comprehensive coverage, more prescriptive requirements, and higher performance thresholds on business-friendly issues, such as those that firms do anyway or those related to industry collective action problems.

These hypotheses illustrate how scholars could revise many of the theories reviewed in section 2 in light of our core methodological critique. We can assess whether doing so is worthwhile in two ways: (1) Does restating theories in terms of the predicted direction of change in scope, prescriptiveness, and policy settings improve our understanding of past research? (2) Does applying the framework reveal patterns of change that other methods failed to discover? Sections 4 and 5 show that our framework meets both tests: its application reveals that the scope, prescriptiveness, and policy settings of forestry certification programs do follow different patterns and that existing theories cannot fully account for these changes.

4 COMPETING US FOREST CERTIFICATION PROGRAMS

We illustrate our methods for measuring stringency through an analysis of forestry certification in the United States, one of the most advanced cases of private regulation. Like

many substantive domains, forestry scholars have carefully dissected components of forestry regulations, both public and private. Yet the unit of analysis in political science scholarship still tends to be broad characterizations of entire policies or only a few of their constituent parts. By drawing on domain-specific scholarship, we conduct a more systematic analysis. The results of this analysis offer the most comprehensive and detailed description of changes in forestry certification standards to date.

Forest certification illustrates how market-based authority can involve formal decision-making modeled on government rulemaking processes, legalistic requirements, and powerful enforcement mechanisms. When product certification programs gain power with consumers and retailers, a timber company's contracts may depend on an audit of their compliance with hundreds of requirements. Noncompliance may be costly. For example, Resolute Forest Products claimed damages of \$100 million CND related to auditor findings of non-conformance (Tigar, 2017). This scale of impact on the industry makes forest certification an important case.

For over 20 years the Forest Stewardship Council (FSC) and Sustainable Forestry Initiative (SFI), have been developing written Forest Management Standards (standards) that promote different conceptions of "sustainable" forest management. The SFI and FSC play a significant role in regulating the forest products industry in the United States, regulating a third of commercially harvested timberland including most corporate-owned timberland (see Figure 1). Many U.S. states support certification as a compliment or alternative to public regulation. For example, some state regulators forgo inspections of FSC-certified forests as legal compliance is part of their FSC audit (Judge-Lord, 2013).

Origin of the FSC: The FSC was established as an international non-profit organization in 1993 by a group of environmental and social advocacy organizations, academics, indigenous groups, and companies. FSC's founders designed its rulemaking procedures as a "democratic" process where members vote on decision-making rules as well as substantive policy (Meidinger, 2003). FSC standards begin with a set of international "Principles and Criteria" (FSC-P&C)

Figure 1: U.S. Timberland by ownership and certification scheme

Sources: AF&PA, 2016; PEFC, 2017; U.S. Forest Service, 2009

that are used by national-level organizations to develop more specific indicators. Our analysis of the FSC in the U.S. thus assesses both the international P&C and the FSC-US national standard.

Origin of the SFI: In 1995, in response to the emergence of the FSC, the U.S.-based industry association, the American Forest & Paper Association, established a forest management standard and required its members (most of the U.S. forest products industry) to support it. Optional third-party auditing was added in 1998, which became mandatory in 2002, the same year that the American Forest & Paper Association made the SFI a legally distinct entity with a rulemaking process that is formally independent, though still largely governed by business stakeholders. The SFI has since been endorsed by the global Program for the Endorsement of Forest Certification (PEFC). The PEFC maintains a set of Sustainable Forest Management Benchmarks intended to guide participating programs, many of which are industry-backed alternatives to the FSC. Unlike the FSC-P&C, the PEFC does not require the SFI and other national-level programs to adopt its benchmarks verbatim. Instead, they are expected to demonstrate the “equivalence” of their standards with PEFC benchmarks. This means that national standards like the SFI’s can have, by some measures, less stringent requirements than PEFC benchmarks.

“Sustainable” Forestry: Like many sectors, there are ongoing debates over acceptable business practices and the appropriate role of public and private regulation in forestry. “Sustainable” forestry has many meanings (McDermott, 2012). For example, some programs use “natural” conditions or functions as benchmarks for sustainability, involving complex choices about what is “natural” and what degree of naturalness is appropriate. In other conceptions, “sustainable” is less associated with naturalistic management and more about the long-term efficiency of production. Such differences manifest in distinct goals and different means to achieve them. A regulation targeting efficiency may require high levels of utilization of trees and tree-parts, whereas a regulation targeting naturalistic management may include requirements to leave economically valuable timber behind for animal habitat or soil health. Disagreements become concrete in the details of such requirements. Thus, a meaningful assessment of similarities and differences between regulations requires attention to detail.

4.1 SCOPE, PRESCRIPTIVENESS, AND POLICY SETTINGS IN FORESTRY

To measure comprehensiveness of scope, we reviewed all FSC, PEFC and SFI standards in effect between 2008 and 2016 to assess their coverage across 48 distinct “key issues” covering a broad scope of forestry requirements, from employee wages and resource utilization to protections for endangered species and indigenous peoples’ rights. These issues were selected in 2008 using an iterative process to disaggregate forestry policies to capture all of the key issues addressed by FSC, PEFC, and SFI requirements (McDermott et al., 2010).

To measure prescriptiveness, we assess the precise wording of the text on each issue. If firms have discretion among performance levels, only the least demanding levels are prescriptive. For example, if firms are required to “maintain or enhance” water quality, the option to merely “maintain” means that there is no mandatory requirement to “enhance” water quality.

To measure policy settings, we offer detailed issue-by-issue comparisons of performance requirements on most of our 48 key issues in the text below and all of them in the online

appendix. This approach is similar to how previous scholars have descriptively compared the SFI and FSC standards on select sets of issues, except with a comprehensive scope of potential issues. Doing so allows us to classify each specific change, the types of issues that changed, and difference on issues that may be important but not (yet) salient in the public debates.

4.2 RESULTS

Here we compare each standard to its previous version and the contemporary version from its competitor. We assess revisions in the FSC- International’s 2012 Revised Principles and Criteria 01-001 Version 5-0 (FSC-P&C) and compare them to revisions in the PEFC’s Sustainable Forest Management Standards 1003:2010. Similarly, we compare the 2010 FSC-US Forest Management Standard Version 1.0 to the FSC-US National Indicators and regional standards it replaced and compare these to the 2005-2009, 2010–2014, and 2015-2019 SFI standards. Unless otherwise specified, “FSC-US” and “SFI” refer to the version of each standard in effect in 2016. We do not fully capture subnational variation. The FSC-US standard recognizes nine different sub-national regions. Some have additional indicators, meaning that, in some states, FSC standards were more prescriptive or had higher performance thresholds than our findings reflect (see the online appendix).

4.2.1 Comparing FSC’s and PEFC’s international requirements

Scope: The FSC-P&C and PEFC maintained a similar scope of issues covered (see the top panel of Figure 2). The PEFC once covered slightly fewer issues than did the FSC-P&C, but its 2010 revisions added new requirements on eight key issues that it previously did not address, making the two programs generally aligned in the scope of issues covered. As of 2015, the FSC P&C covered three potentially costly issues that the PEFC still did not: carbon emissions, restrictions on conversion to plantations, and worker wage requirements (see the middle panel of Figure 2). PEFC covers two issues relating to public perceptions that

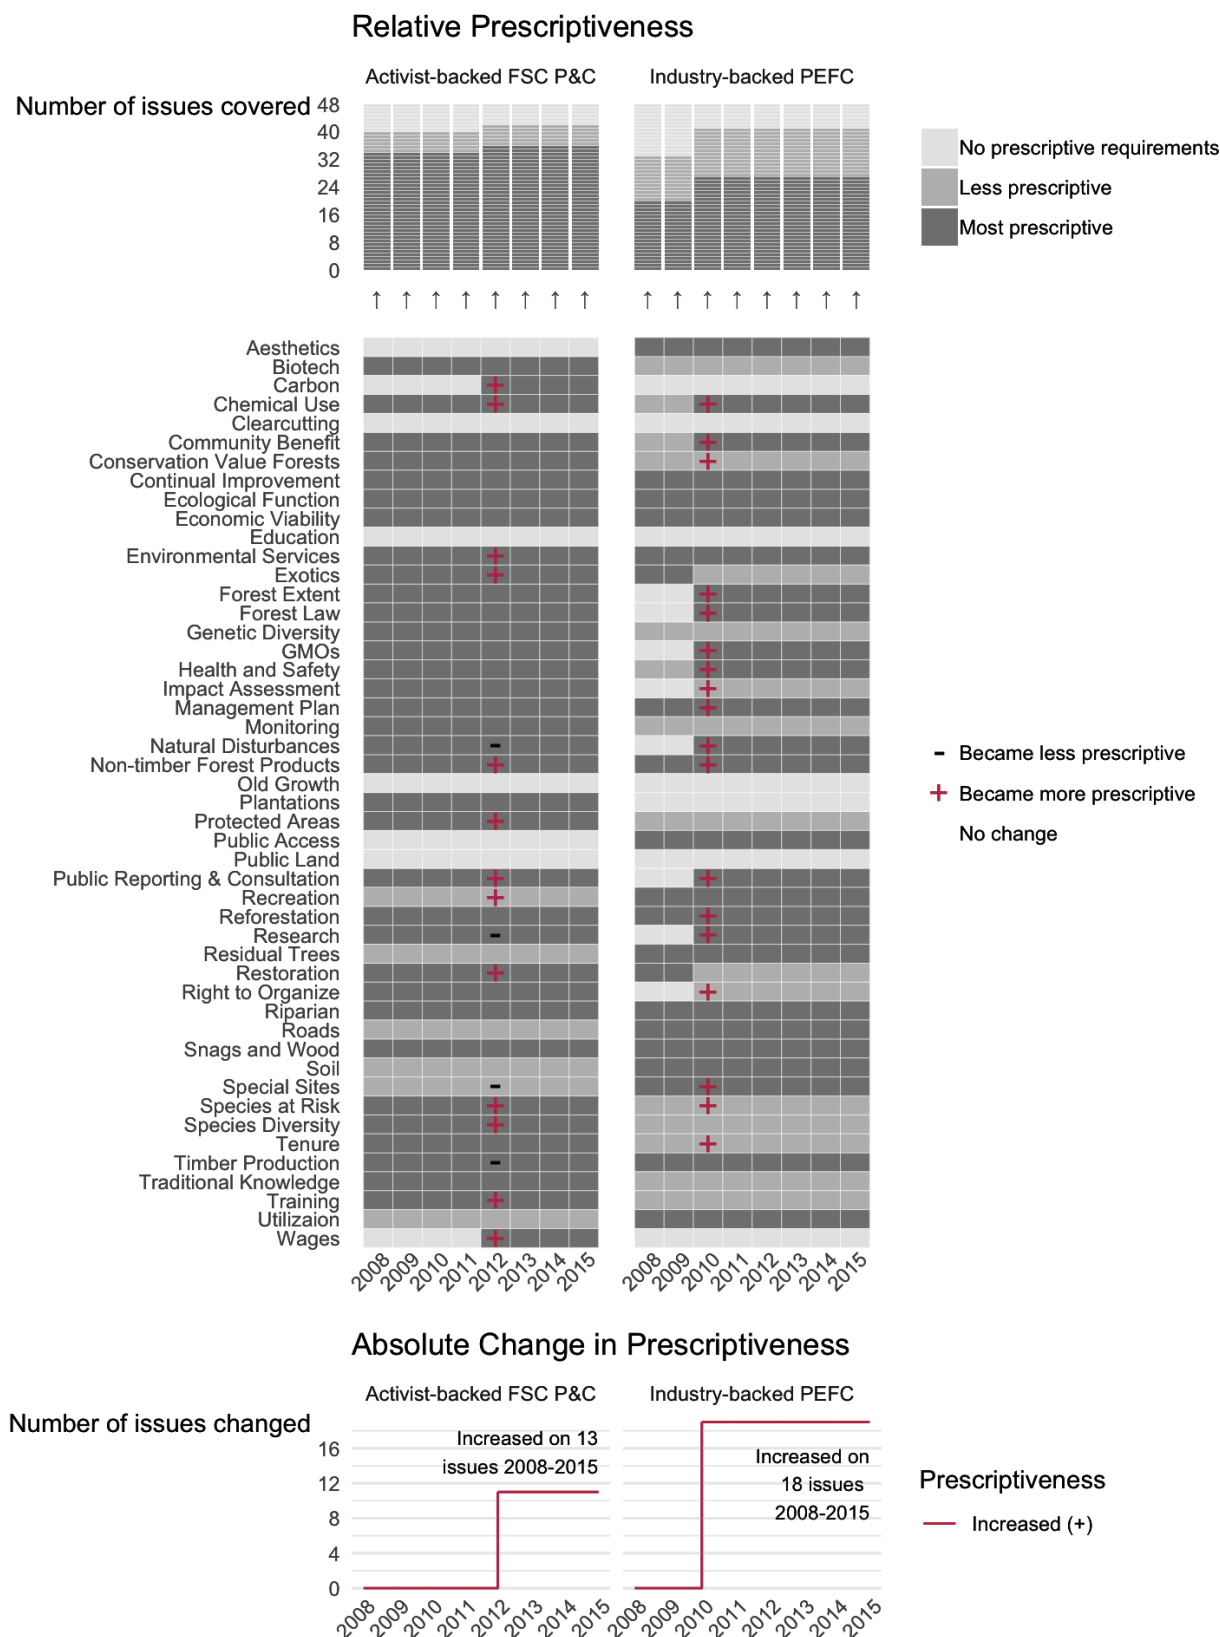

FSC-P&C do not: managing the aesthetic impacts of forestry and allowing public access.

Prescriptiveness: Overall, the FSC maintained more prescriptive requirements in its Principles & Criteria than the PEFC benchmarks (the top panel of Figure 2), but the PEFC moved closer to the FSC-P&C in some key areas (the middle panel of Figure 2). These include additional requirements on issues including indigenous rights, community benefits, and public reporting and consultation (see the online appendix for specific language). The PEFC became at least as prescriptive as the FSC-P&C on over half of key issues. In absolute terms, the PEFC increased prescriptiveness on 19 key issues and decreased on none, whereas the FSC-P&C increased on 13 and decreased on four. Yet significant differences remain. The FSC-P&C contain more prescriptive language on most ecological criteria, including protected areas and restrictions on conversion to plantations.

Both programs have more procedural requirements than substantive requirements (i.e., they are more focused on process than outcomes). Despite convergence in the PEFC's revised requirements, the FSC-P&C remained more prescriptive than PEFC requirements on 17 of the 48 key issues whereas PEFC requirements are more prescriptive on nine issues, with both programs being equally prescriptive on 19 issues. Because the PEFC started at a lower level but increased prescriptiveness on more issues than did FSC P&C, the resulting pattern is an "upward convergence" (the bottom panel of Figure 2).

Policy settings: One particularly controversial issue is the conversion of natural forests to timber plantations. Both programs permit certification of natural forest converted to plantation forestry under "justifiable circumstances," which differ qualitatively between the two programs. For the FSC, this means that conversion has "clear, substantial, additional, secure, long-term conservation benefits." For the PEFC it means that conversion must have "long-term conservation, economic, and social benefits." They also differ regarding the extent of forest conversion allowed. The FSC-P&C allow companies to convert "limited areas" while the PEFC allows "small proportions of forest types." Both standards specify that conversion must not damage culturally or socially significant areas, but whereas PEFC suggests that

Figure 2: Scope and Prescriptiveness of FSC P&C and PEFC 2008-2015

forests should only be certified if the conversion occurred before 2011, the FSC-P&C require that conversion occurred before 1994, significantly different thresholds.

Both FSC-P&C and PEFC added new requirements on socio-economic issues, land tenure rights, and stakeholder consultations. In addition to citing the UN Declaration on Rights of Indigenous Peoples, both programs included criteria that require free, prior and informed consent of indigenous peoples and local communities. The FSC-P&C required “free and informed consent” concerning control over forest operations and compensation for the use of traditional knowledge. Both standards also recognized legal, traditional, and customary rights. However, the FSC-P&C are more prescriptive, defining topics on which forest managers must consult with indigenous peoples, while the PEFC standards are more procedural, requiring only that engagement takes place. The FSC’s criteria regarding public consultation include special obligations to “affected stakeholders” compared to “interested stakeholders” while PEFC requirements regarding “local people and other stakeholders” are the same.

Both programs cover similar ecological issues, with some qualitative differences. Both FSC-P&C and PEFC requirements prohibited the use of GMOs in the area being certified, with some possible flexibility should scientific evidence affirm the safety of GMO trees. FSC-P&C allow documented and monitored use of biological control methods but prohibited a specific list of “Highly Hazardous Chemicals.” The PEFC added prohibitions on pesticides that remain biologically active and highly toxic pesticides where viable alternatives are available. The PEFC explicitly required managers to avoid chemicals where they threaten water quality, while FSC-P&C water protection criteria were less explicit. Both programs had similar requirements for sustainable production of timber and non-timber forest products (NTFPs), but the FSC-P&C set a higher level of protection for animal habitat. While the FSC-P&C required protection of rare and threatened species and their habitats, the PEFC only required that protected and endangered species not be exploited for commercial purposes and that managers take measures for their protection “where necessary,” without defining these conditions.

Summary: Overall, while the PEFC added more requirements concerning indigenous rights and labor standards and came to cover a similar scope of issues to the FSC P&C, the FSC-P&C remained more prescriptive on social issues and significantly more prescriptive on ecological issues. Compared to the prescriptiveness of the FSC-US and SFI described below, the FSC-P&C and PEFC requirements exhibited more convergence on both scope and prescriptiveness (compare Figures 3 and 4) though many differences in policy settings remained.

4.2.2 Comparing the FSC-US and SFI

Scope: Consistent with the international level, the activist-backed FSC-US program and industry-backed SFI program in the United States address a similar scope of issues, but the FSC-US is more prescriptive on most (the top panel of Figure 3). As of 2016, the FSC-US did cover six potentially costly issues that the SFI did not; community benefit requirements, forest extent restrictions, required impact assessments, protected area restrictions, restoration requirements, and indigenous tenure protections (the middle panel of Figure 3). The SFI, in turn, covered one issue that the FSC-US did not: contributing to forestry research. Both programs added requirements on greenhouse gasses in 2010. SFI allows for the conversion of natural forests to plantations if ecological impacts are not significant and the converted forest type is not rare, but in 2015, SFI added a requirement to conduct an assessment of these impacts. Yet, the FSC-US still maintained more prescriptive requirements, only allowing certification of plantation forests if they were converted from natural forests before 1994. FSC-US also requires a portion of these plantations to be maintained as, or restored to, natural conditions.

Prescriptiveness: In 2008 the FSC-US was more prescriptive on 36 of 48 key issues, and the SFI was more prescriptive on five issues. These five are some of the most “business-friendly” issues: continual improvement of management planning, educating the public about forestry, contributions to forestry research, worker training, and efficient material utilization. In 2016

the FSC-US was more prescriptive on 37 key issues, and the SFI was more prescriptive on the same five issues. The two standards were equally prescriptive on five issues. This means that the FSC-US had the “most prescriptive” requirements—those as prescriptive or more than any other program—on 42 issues and the SFI had the most prescriptive requirements on 10 (the top panel of Figure 3).

Counting changes made to the FSC-US and SFI standards between 2008 and 2016 reveals an “upward diverging” pattern, where the FSC-US became more prescriptive than did the SFI (the bottom panel of Figure 3). Of 48 key issues, the FSC-US became more prescriptive on 20, whereas SFI became more prescriptive on 12 (eight in 2010, one more in 2013, and three more in 2015).

Policy Settings: Issues such as clearcut size limits and limits on harvesting near streams clearly illustrate enduring differences between the SFI and the FSC-US because we can compare policy settings on these issues both qualitatively and quantitatively. Qualitatively, the FSC-US increasingly restricts the size and shape of clearcuts to reflect “natural disturbance” and maintain ecological functions regardless of how it looks, whereas the SFI emphasizes “the visual impacts of forestry” and requires rapid site “green-up.” Quantitatively, the SFI limited clearcuts for all forest types to an average of 120 acres with no maximum and no limits for harvesting with 20 percent tree retention (i.e., intensive but not clearcut harvesting). In contrast, the FSC-US limits clearcuts to a 40-acre average and 80-acre maximum, with additional restrictions based on region and forest type. The FSC-US also limits harvesting with 20 percent tree retention to a 100-acre average and 80-acre maximum, with further restrictions based on region and forest type (Figure 4).

For harvesting near streams, the FSC-US lists specific requirements for water quality, habitat, and other objectives with a focus on restoration. Additionally, most FSC-US regions have numeric minimum riparian buffer zones (Figure 5). In 2015, SFI expanded its definitions of riparian areas but continued to allow more discretion regarding what managers include in plans to protect water resources with no numerical minimum buffers beyond those in state

Figure 3: Scope and Prescriptiveness of FSC-US and SFI 2008-2016

laws and best management practices. While we can only compare most other policy settings qualitatively, the FSC-US clearly requires higher levels of performance on many social and ecological issues (Table 5).

Figure 4: Limits on Clearcut Size

While both the FSC-US and SFI became more prescriptive, they did so to different degrees and in different areas. The SFI's changes in 2010 emphasized issues related to industrial capacity (e.g., worker training requirements) and reputation (e.g., managing the visual impact of harvesting, communicating with stakeholders about logging, and educating the public about forestry), issues where SFI already had the most prescriptive requirements. Changes made the same year by the FSC-US emphasized conservation-oriented forestry while removing a training requirement.

The bulk of the divergence occurred on ecological requirements like protecting habitat, where the FSC-US became more prescriptive while the SFI stayed constant or, in the case of preserving old-growth forests, decreased in prescriptiveness. Regarding protected areas, the FSC-US continued to require that managers preserve representative samples of habitats, but, since 2010, also requires an assessment of the adequacy of permanent protections. SFI's

Figure 5: Limits on Harvesting Near Streams

Table 5: Qualitative Levels of Performance Required for Certification

Issue	Activist-backed FSC-US	Industry-backed SFI
Indigenous peoples' rights	Recognize and uphold rights, customs, culture, including UNDRIP. No threat to rights or resources. Free, prior, and informed consent on public and private lands. Engage indigenous peoples and consult with affected groups. Cooperate to identify and protect significant sites. Compensate for indigenous knowledge and utilize as requested.	A written policy acknowledging a commitment to recognize and respect rights.
Public Reporting and Consultation	Required on public and private lands.	Required on public lands.
Forest conversion to non-forest	Prohibited except limited areas where clear, substantial, additional, secure, long-term conservation benefits.	No specific policy.
Old growth forest	Old growth is normally mapped as conservation forest. Only restoration management on public land. Legacy trees not harvested. Maintain structure, composition, and processes. A portion of the forest is restored where old growth would naturally occur.	Support and participate in programs for old growth conservation—no identification or restoration requirements.
Protected areas	Conserve or restore a representative area of natural ecosystems. Assess and maintain environmental values and necessary conservation measures.	No specific policy.
Threatened and Endangered Species	Survey and report or assume vulnerable and imperiled species are present. Maintain habitat & viable populations.	Program to protect threatened and endangered species at known sites. Protect viable populations of imperiled species.
Workers' right to organize	Workers are free to associate and advocate. Develop dispute resolution.	Obey laws. Train on worker rights.
Wages	Written commitment to comply with social law prevailing wage.	Train on wage rules.
Safety	Safety guidelines posted. Contracts include safety. Records kept.	Written commitment to comply with OSHA. Training on OSHA

requirements for protected areas continue to be encompassed mainly by its requirements to protect imperiled species. SFI continues to require plans to identify and protect moderately to highly valuable known populations of imperiled or critically imperiled species (designations G1-G2). In contrast, the FSC-US expanded the scope of species requiring protection in 2010 to include natural heritage species and candidate species (designations G1-G3, S1-S3, N1-N3). The FSC-US added requirements to conduct surveys for any at-risk species potentially present or presume that listed or candidate species are present if the forest is in a species' range. For old-growth forests, in 2010, the FSC-US added prescriptive requirements to restore a portion of old-growth forests where they would naturally occur, and it continues to demand protection measures that prohibit harvesting in most cases. In 2010, SFI removed a requirement to maintain sufficient old-growth acreage to maintain biodiversity, but in 2015 added a requirement to participate in conservation planning.

The FSC-US and SFI's changing requirements to designate and protect conservation areas exemplify their overall upwardly diverging prescriptiveness, with the SFI adding some prescriptive requirements but the FSC-US adding even more prescriptive requirements. In 2010, the SFI added new requirements to collect data on "Forests of Exceptional Conservation Value" (FECV), which we compare to the FSC's requirements for "High Conservation Value Forests" (HCVF). Also, in 2010, the FSC-US added language regarding monitoring and adaptive management of HCVFs. While the acronyms and even the additional language appear similar, the SFI allowed more flexibility in FECV management. HCVFs under the FSC-US required significantly more than baseline practices (Newsom and Hewitt, 2005), while SFI's FECV requirements have been criticized as not significantly exceeding legal baselines (state and federal endangered species acts) which already protect threatened and endangered species. The FSC-US then added even more prescriptive requirements requiring certain areas to be designated HCVFs and prescriptive accountability mechanisms for HCVF management.

Summary: Overall, each program had distinct areas in which its requirements were more prescriptive. For the FSC, these requirements tended to demand that forest operations

“resemble natural processes” and “maintain ecosystem function.” This language appeared more frequently and forcefully in the 2010 standard concerning issues including clearcutting, riparian management, HCVEs, protected areas, old-growth forests, snags and downed wood, residual trees, genetic diversity, plantations, restoration, natural disturbance, non-timber forest products, soil protection, road building, and management planning. In contrast, the SFI was most prescriptive on issues such as material utilization, research, training, education, and public reporting and consultation. The eight key issues on which the SFI increased prescriptiveness in 2010 also reflect the SFI’s focus on industry capacity and reputation. These included aesthetics, public reporting, education, training, and utilization.

The 2015 changes to the SFI standard reflect a different tack. In contrast to the previous focus on more “business-friendly” issues related to industry capacity and reputation, the three issues on which the SFI increased prescriptiveness in 2015 reflect social and ecological goals. These include prohibiting the use of certain toxic chemicals, restricting the circumstances under which natural forests can be converted to plantations, and requiring a written policy to recognize and respect indigenous rights.

5 DISCUSSION

5.1 OVERALL COMPARISON

By distinguishing different types of stringency on a comprehensive set of issues, our framework improves upon blunt measures of “high” or “low” standards based on generalizations or on only a few issues.

Overall our results are consistent with the expectation that activist backed programs have higher levels of more costly types of stringency. On ecological goals, the FSC-US standard was significantly more stringent than the SFI standard on both scope and prescriptiveness dimensions. On social goals, results are more mixed. On scope, the FSC-US standard protected land tenure and requires that local communities benefit from harvesting in ways

that were unmatched by SFI’s standard. Numerically, FSC-US had a broader scope of social benefits, but the programs did present tradeoffs between conceptions of the public good. On prescriptiveness, the contrast was more stark, with the FSC-US standard having significantly more prescriptive requirements on most social issues. On policy settings, the two programs had significant differences. On labor standards and indigenous rights, the FSC-US required higher wages and more attention to rights than did the SFI. In short, by conventional definitions of what counts as a social issue, by most qualitative comparisons, and certainly in terms of prescriptiveness, the FSC-US standard was more stringent than the SFI standard on social issues.

On more business-oriented goals such as efficiency (e.g. levels of cut tree utilization), industry capacity (e.g. workforce training and research), and industry reputation (e.g., public education and aesthetics), the patterns were largely reversed. SFI was slightly broader in scope, requiring contributions to research where FSC did not, was more prescriptive, and required increasingly demanding performance levels on many business-friendly issues.

5.2 PATTERNS OF CHANGE

In most years between 2008 and 2016, neither the FSC nor the SFI changed on any issue (the center cell in Table 4, “equilibrium”).

When they did change, upwardly diverging prescriptiveness was the dominant pattern. Most changes for both programs occurred in 2010 where the overall pattern was divergence, rather than convergence or stability. For all sixteen issues on which only the FSC-US added requirements, it already had the more prescriptive requirements, and almost all of these additions address ecological problems. Similarly, for three out of the four issues on which only the SFI added requirements, the SFI already had more prescriptive requirements.

The vast majority of changes (twenty-one of twenty-seven issues changed) fit a pattern where one program increased prescriptiveness while the other did not (or in one case, increased to a lesser degree) and the program that increased stringency already had the more prescriptive

Table 6: Patterns of Change in Prescriptiveness among U.S. Forestry Certification Programs on 48 Key Issues

2010

	Converging	Parallell	Diverging
Increasing	1	3	18
Opposing or Equilibrium	0	21	3
Decreasing	2	0	0

2015

	Converging	Parallell	Diverging
Increasing	3	0	0
Opposing or Equilibrium	0	45	0
Decreasing	0	0	0

requirements. On eighteen issues, the less prescriptive program stayed the same, leading to upward divergence. On three issues, the less prescriptive program decreased prescriptiveness, leading to opposing divergence (see Table 6).

Convergence was rare. In 2010, upward convergence only occurred where FSC-US added requirements on the issue of “continual improvement” of harvesting operations, an issue usually associated more with the SFI. This outcome is interesting because scholars generally predict that less stringent private regulations will converge toward “benchmark” standards like FSC’s (Overdevest, 2005, 2010). Instead, we find the FSC-US ratcheting up prescriptiveness on an issue where its industry-backed competitor had more stringent requirements. Indeed, most studies overlook the possibility that industry-backed standards like the SFI may be more stringent on some issues and thus fail to theorize about dynamics that could cause this. We see downward convergence only on the issues of “community benefits” and “tenure rights,” where the more prescriptive FSC-US removed requirements, thus moving closer to SFI.

Parallel change was also rare. An upward parallel change occurred on only three issues in 2010: forest management planning, controlling carbon emissions, and reporting and

consultation, where both programs added requirements. We classify the addition of protections for riparian zones by both SFI and FSC-US as another case of upward divergence rather than upward parallel change because the requirements for riparian protection added by the FSC-US were more prescriptive than those added by the SFI. No issues exhibited downward parallel change, as “race to the bottom” theory anticipates.

After the significant revisions of both programs in 2010, only the SFI updated its requirements, mostly in 2015. In contrast to the 2010 changes, the pattern in 2015 was a moderate upward convergence. SFI increased prescriptiveness on three issues where it did not already have the most prescriptive requirements. While a much smaller scale of change than 2010, this upward convergence is notable because it focuses on regulating toxic chemicals, plantations, and harvesting on tribal lands, which likely have net costs rather than benefits for the industry.

5.3 IMPLICATIONS FOR THEORY

Applying our framework to the case of forestry certification reveals how one could reach different conclusions by looking at different dimensions of change. If focusing only on program scope, one would find little support for any theory predicting change—either convergence or divergence. If focusing only on prescriptiveness on ecological issues, one would find divergence, with the activist-backed FSC-US becoming more prescriptive at a faster rate than the industry-backed SFI. But if focusing only on prescriptiveness on industry capacity and reputation issues, one would find the opposite, with the SFI becoming more prescriptive at a faster rate than the FSC-US. While certainly inconsistent with “race-to-the-bottom” theories, the overall upward by diverging trajectories of the SFI and FSC-US do not exactly fit a “race to the top” either.

Our results do support, with some caveats, hypotheses 1.1, 2.1 , and 2.2 outlined in Section 2.3. We ended up with no evidence either way on hypothesis 1.2.

Regarding H1.1, the industry-backed program often had language similar to that of the

activist-driven standard (i.e., it had a similar scope), but often lacked mandatory performance thresholds (i.e., it did not have similar prescriptiveness). If “talk is cheap,” but prescriptive requirements are costly, it makes sense that an industry-backed program would cover similar issues as its competitor without adopting costly performance thresholds. This result suggests that any test of theories about the cost of compliance must distinguish between measures of stringency based on policy scope or prescriptiveness. Regarding H1.2, we cannot tell whether changes in scope are more likely to be matched by competing programs because neither program changed significantly in the scope of issues addressed. Both programs did begin regulating carbon emissions in 2010, but it is unclear if this change in scope is one program reacting to the other or both programs responding to a third causal factor.

Regarding H2.1, we find differentiation between the FSC-US and the SFI; the activist-backed program was more comprehensive in scope, was more prescriptive, and had higher performance levels on issues that cost firms’, while the industry-backed program was more comprehensive in scope, was more prescriptive, and had higher performance levels on issues that create net utility for the industry. Hypothesis 2.2 posits that the same kind of differentiation will drive policy change. This aligns with changes to the FSC-US and SFI in 2010, but less so in 2015. More research is needed to test these and other hypotheses, using similarly precise and comprehensive measures of regulatory stringency. Specifically, while “ratcheting up” theories anticipate the general upward direction we observe, more attention is needed to explain why programs may increase prescriptiveness on different issues, especially issues where they already have the more stringent requirements.

5.4 INDUSTRY-BACKED CERTIFICATION PROGRAMS AS A FORM OF COLLECTIVE ACTION

Our finding that the SFI and FSC-US were each more prescriptive and continued to become more prescriptive on qualitatively different issues highlights how industry-backed certification programs can serve their industry in two ways. First, they provide individual firms with a

service—a signal of “social responsibility” that requires a credible third party. Such a signal would be more expensive to send by complying with an activist-backed regulation. Second, they provide a mechanism for an industry to improve its collective reputation and capacity by coordinating contributions to collective goods, a common function of industry associations.

Regarding the first, industry-backed programs are often created to save firms money by offering a label that sends “green” or “socially responsible” signals in the market without some of the more costly demands of activist-backed programs or public regulations. Such signals are often based on perceived stringency, which may vary from actual stringency.² Nevertheless, maintaining legitimacy may require some prescriptive requirements on costly issues. On these issues levels of prescriptiveness and policy change are likely driven by competition with activist-backed standards.

Regarding the second, the fact that the SFI developed more prescriptive standards than the FSC-US on several issues is inconsistent with the predictions that competition between industry-backed and activist-backed competition will lead to a “race to the bottom” on all issues. It is also inconsistent with the prediction that activist-backed standards will be more prescriptive on all issues. However, the substance of these issues suggests that these requirements are unrelated to competition with the FSC. Instead, SFI had the most prescriptive requirements for actions that firms may take anyway—like training workers and maximizing efficiency—or that may be driven by their own collective action problems—like managing the visual impact of harvesting and sector-level reputation. Likewise, the three issues on which only the SFI changed—maximizing the utilization of cut trees, public education, and worker training—reflect concerns for the efficiency, reputation, and capacity of the forest products industry. Educating the public about forestry and training workers may not exclusively benefit individual firms, but given the broad adoption of SFI certification, such requirements may provide collective benefits for the sector in the form of a positive public image and skilled workforce.

In short, where the SFI developed more prescriptive requirements than the FSC, it

required things that firms may do anyway (e.g., train workers or educate the public), but have additional collective benefits the more widely they are adopted. While unforeseen by existing theories, the fact that the SFI is more prescriptive on some issues is unsurprising if these requirements provide net benefits to the sector regardless of activist pressures or consumer demands.

6 CONCLUSION

Scholars have made substantial progress in developing theories of how economic and political forces shape the substance of private regulations, and how these different requirements then affect levels of adoption and compliance. We have argued that testing these theories requires more precise statements of the types of policy substance to which they apply and research that measures change across programs and over time. Our framework for measuring regulatory stringency, and for using longitudinal data to classify patterns of change, offers a foundation for further research about how competing regulatory programs compare, how they evolve, and why. There is no perfect way to compare incommensurate policies. We have nonetheless made our best effort to offer a method to do so. By applying this method, we have systematically quantified differences that can be quantified and described as richly as possible those comparisons that one can only make qualitatively.

Through the case of forestry standards in the U.S., we show what can be gained by careful measurement of regulatory stringency and policy change across a comprehensive scope of issues in a specific domain. Our results show different patterns depending on whether one looks at policy scope, prescriptiveness, or specific policy settings. Careful measurement uncovered trends that previous scholarship has missed and which contradict the predictions of several dominant theories. It also reveals that apparent empirical debates in the literature are the result of research design choices. Some scholars chose a few key issues and found convergence. Others looked broadly and did not see it. We have looked both precisely and broadly and found both conclusions were correct but incomplete. Activist-backed and

industry-backed programs converged in policy scope on a few issues, but overall, their scopes have seen little change. Furthermore, we found these programs to have diverged overall on prescriptiveness, because, while both standards “ratcheted up,” they did so at different rates and on different policy issues. We hope that this deep dive into defining regulatory stringency and policy change in one domain not only enables scholarship on the causes of public and private regulation in forestry but that it also offers a model for similar research in other policy domains.

This approach also has practical value. First, the power dynamics among groups that promote programs like the FSC or the SFI have created an environment in which competing claims about what exactly each program requires and how this has changed confuse buyers. The politics of private regulation revolve around “public comparisons that would resolve the debate about whose standards were higher” (Overdevest, 2010). We offer concepts to clarify what “higher” standards may mean. Second, it is impossible to measure the impact of a set of regulatory requirements without disentangling their component parts. Thus, our analysis of written requirements is a necessary first step for efforts to assess the effects on the ground.

Most importantly, our framework and analysis offer a model for careful measurement of policy change as a variable. It is tempting to take shortcuts by making broad generalizations or by selecting what is easy to measure or what others have highlighted. However, if we aim to build testable theories or collect the kinds of evidence needed to test existing theories, our study illustrates the benefits of defining policy change in ways that can be applied across programs and over time. Doing so will not only improve the quality of research and theory, it may also uncover entirely new puzzles and insights.

NOTES

¹While assessing a comprehensive set of issues reduces the risk of omitting key issues on which regulations may vary, it is often time consuming and costly. Scholars may thus opt for a limited scope, as long as they clearly describe their scope relative to the potential set of comparisons. A comprehensive approach is necessary, however, to assess claims about the scope of regulations (such as the hypotheses from section 2.3).

²While our framework clarifies differences in actual stringency between activist- and industry- backed programs, which program one prefers will still depend on one's problem definitions and values. What we do know is that, on many issues, industry-backed programs address the same issues as activist-backed programs with language that might give the impression of equivalence in stringency but contain substantially fewer prescriptive requirements. We show that seemingly similar looking language requires very different levels of performance. For example, the SFI requirements for "Forests of Exceptional Conservation Value" (FECV) are much less prescriptive than the FSC-US requirements for "High Conservation Value Forests" (HCVF), despite their similar language (also see (e.g. Figures 5 and 4 and Table 5)). The extent to which this helps firms coordinate to maximize the impression of stringency while minimizing the costs of doing so is a question for future research.
